addebug - Modifies Makefile(s) to add debug info

```
adddebug [-k] [-r] [-n]
```

DESCRIPTION

adddebug modifies the *Makefile* in the current directory (and optionally in its subdirectories) to add debug info (**-g3**). It will also remove optimisations (**-O[1-9]**).

This utility is part of the KDE Software Development Kit.

OPTIONS

- k** Keep optimisations (do not remove **-O[1-9]?** flags which are removed by default).
- r** Recursively search through all subdirectories of the current directory and operate on every *Makefile* that is found.
- n** compile without NDEBUG and NO_DEBUG being defined (makes **kdDebug** calls work)
